# Reference Material

These slides are based on:

- ▶ The referred papers in the slides
- ▶ JPA: parts of chapter 9 to 12
- ▶ DW: parts of chapter 5 to 7

# Protocol APIs

By this we mean, on a high level, a server that:

# Protocol APIs

By this we mean, on a high level, a server that:

- ▶ holds secrets where clients can make queries

# Protocol APIs

By this we mean, on a high level, a server that:

- ▶ holds secrets where clients can make queries
- ▶ holds secrets that clients can interact with

# Protocol APIs

By this we mean, on a high level, a server that:

- ▶ holds secrets where clients can make queries
- ▶ holds secrets that clients can interact with

# Protocol APIs

By this we mean, on a high level, a server that:

- ▶ holds secrets where clients can make queries
- ▶ holds secrets that clients can interact with
- ▶ combine inputs to verify batches at once

# Protocol APIs

We will look at examples where a client can:

- ▶ extract secret signing keys
- ▶ forge signatures
- ▶ trick a verifier

Several of which are similar to the weekly problems.

We will also look at some mitigations to these issues.

# Recap: Schnorr Signatures

Let  $\mathbb{G}$  be a group of prime order  $p$  and let  $g$  be a generator for  $\mathbb{G}$ . Denote by  $\text{pp}$  the public parameters  $(\mathbb{G}, g, p)$ .

Let  $H$  be a cryptographic hash function that outputs uniformly random elements in  $\mathbb{Z}_p$ .

Let the secret key  $\text{sk} \leftarrow_{\$} \mathbb{Z}_p$  be sampled uniformly at random, and let the public key be  $\text{pk} = g^{\text{sk}}$ , where  $\text{pk}$  is made public.

# Recap: Schnorr Signatures

The Schnorr signature of message  $m$  is computed as:

1. Sample random  $r \leftarrow \mathbb{Z}_p$  and compute  $R = g^r$ .
2. Compute the output challenge as  $c = H(\text{pp}, \text{pk}, m, R)$ .
3. Compute the response  $z = r - c \cdot \text{sk}$ . Output  $\sigma = (c, z)$ .

To verify the signature, compute  $R' = g^z \cdot \text{pk}^c$  and check if  $c \stackrel{?}{=} H(\text{pp}, \text{pk}, m, R')$ . If correct, accept, and otherwise reject.

# Distributed Schnorr Signatures

Assume that two parties  $P_0$  and  $P_1$  wants to compute a joint Schnorr signature. Then  $P_i$  does the following:

KGen :

- ▶ Sample random  $sk_i \leftarrow \mathbb{Z}_p$  and compute  $pk_i = g^{sk_i}$ .
- ▶ Send  $pk_i$  to party  $P_{1-i}$ . Set  $pk = pk_0 \cdot pk_1 = g^{sk_0+sk_1}$ .

This is called an additive secret sharing of the signing key.

# Distributed Schnorr Signatures

Sign:

- ▶ Sample random  $r_i \leftarrow \$ \mathbb{Z}_p$  and compute  $R_i = g^{r_i}$ .
- ▶ Send  $R_i$  to party  $P_{1-i}$ . Set  $c = H(\text{pp}, \text{pk}, m, R_0 \cdot R_1)$ .
- ▶ Send the response  $z_i = r_i - c \cdot \text{sk}_i$  to party  $P_{1-i}$ .

The signature  $\sigma = (c, z_0 + z_1)$  can be verified as usual.

**Question:** How can a malicious client  $P_0$  interacting with an honest (protocol API)  $P_1$  break this signature scheme?

# Potential Attacks

- ▶ The adversary can control the nonce values
- ▶ Repeated nonces for different  $m$ 's leak  $sk_1$
- ▶ (The adversary can bias the secret-public keys)
- ▶ (The adversary can abort to deny signatures)
- ▶ (All parties need to be online to sign together)

# Mitigations in Practice

- ▶ Send hashes in an extra round in KGen and Sign
- ▶ Send  $h_i = H(pk_i)$  then  $pk_i$  and  $h'_i = H(R_i)$  then  $R_i$
- ▶ (If signatures are deterministic we need other solutions)
- ▶ Make it a  $t$ -out-of- $n$  signature instead of 2-out-of-2

## Proactive Two-Party Signatures for User Authentication

# BLS Signatures

Let  $\mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T$  be groups of prime order  $p$  with generators  $g_1, g_2, g_T$ . Let  $\hat{e} : \mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$  be a bilinear pairing such that  $\hat{e}(g_1^a, g_2^b) = g_T^{a \cdot b}$  for all  $a, b \in \mathbb{Z}_p$  and  $H$  be a cryptographic hash function that outputs uniformly random elements in  $\mathbb{G}_2$ .

Let the secret key  $sk \leftarrow \mathbb{Z}_p$  be sampled uniformly at random, and let the public key be  $pk = g_1^{sk}$ , where  $pk$  is made public.

A signature is computed as  $\sigma = H(m)^{sk}$ . The verifier checks  $\hat{e}(g_1, \sigma) = \hat{e}(pk, H(m))$ . If correct; accept, otherwise reject.

# BLS Multisignatures

We can efficiently verify many signatures at once:

- ▶ Given many triples  $(pk_i, m_i, \sigma_i)$ , compute:  $\sigma = \prod_i \sigma_i$
- ▶ Verify all signatures as:  $\hat{e}(g_1, \sigma) = \prod_i \hat{e}(pk_i, H(m_i))$
- ▶ If all messages are identical:  $\hat{e}(g_1, \sigma) = \hat{e}(\prod_i pk_i, H(m))$
- ▶ If the same signers we can aggregate keys:  $apk = \prod_i pk_i$

**Question:** Fix  $m$  and  $pk_0$ , how can an adversary forge a signature for  $pk_0$  that verifies in the aggregated setting?

# Potential Attacks

- ▶ Set  $pk_1 = g_1^\alpha \cdot (pk_0)^{-1}$  and signature  $\sigma = H(m)^\alpha$
- ▶ Then  $\hat{e}(g_1, \sigma) = \hat{e}(g_1^\alpha, H(m)) = \hat{e}(pk_0 \cdot pk_1, H(m))$

# Mitigations in Practice

- ▶ Require a proof for secret key knowledge
- ▶ Only aggregate distinct messages each time
- ▶ Verify a random linear combination of keys/signatures

# DL Parameters

For security of (EC)DH and (EC)DSA, we need to work in prime order (sub-) groups for the discrete logarithm problem to be hard. What happens if this is not the case?

# DL Attacks

Recall from earlier that:

- ▶ Hardness of DL depends on the divisors  $p$  of the order
- ▶ We have generic attacks that runs in  $\sqrt{p}$  time
- ▶ We have sub-exponential attacks for finite field groups

# Faulty parameters

What information might leak if:

- ▶ The order of the (sub-) group is not prime?
- ▶ The element is not in the correct (sub-) group?

Use  $g^{\text{sk}} \bmod p$  as an example (EC in weekly problems).

**Question:** How might this happen in practice?

# Mitigations in Practice

Always verify:

- ▶ given parameters
- ▶ input elements
- ▶ output elements
